Executive summary

Of 1,283 scored U.S. stock and ETF calls, 646 were directionally correct and 637 were incorrect over 21 trading sessions. The directional hit rate was 50.4%, and the market-relative hit rate was 47.9%. Mean signed return relative to SPY was +0.013%, equivalent to approximately 1.3 basis points.

The results do not establish an aggregate one-month forecasting advantage or a basis for systematically reversing the recommendations. The study applies uniform forward price windows. It does not evaluate each call against its stated timing or price target, including views expressed for the current day or several years.

Primary window: 21 sessions	Result
Asset views identified (all classes)	2,069
Stock / ETF views identified	1,465
U.S. equity / ETF calls scored	1,283
Directional hit rate	50.4%
Market-relative hit rate	47.9%
Mean signed price return	+0.40%
Mean signed return versus SPY	+0.01%

Principal findings

- The 95% bootstrap interval, clustered by entry month, is 45.9% to 54.8% for directional accuracy and -1.27% to +1.46% for mean market-relative return.
- Valuation calls recorded 55.6% directional accuracy across 99 outcomes, compared with 44.9% across 138 momentum calls. These category results are exploratory and do not establish a forecasting rule.
- Market-relative accuracy declines to 45.9% after suppressing repeated calls and to 46.1% when each security receives equal weight. Frequently cited securities affect the aggregate result.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Source coverage

The sample covers posts published from October 2, 2021 through October 2, 2026, using New York dates. Classification covered all 11,591 retrieved posts authored by Jim Cramer, including original posts, his replies and his commentary on quoted posts. The analysis excludes third-party quoted text, native retweets, speech in videos and linked articles. Historical prices end on October 1, 2026; the provider had not supplied October 2 stock bars when the dataset was finalized.

Archive coverage and identified calls

Retrieved public posts for 2021-10-02 to 2026-10-02; boundary years may be partial.

All 61 monthly searches reached the end of available results.

Unavailable or deleted text, video-only calls and linked-article calls cannot be verified.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

The source audit reconciled 11,591 public posts across 61 monthly searches. All searches reached the end of available results. Retrieved results do not establish historical completeness. Deleted and inaccessible text remain unverifiable.

Backtest methodology

Choice	Rule
Entry	Daily opening price on the first SPY trading session after the post's New York publication date.
Exit	Same instrument's daily open h SPY session intervals after entry, on the exact required date.
Prices	Split-adjusted price returns, excluding dividends, transaction costs and stock borrow.
Primary horizon	21 SPY trading-session intervals, chosen before inspecting returns.
Directional hit	A positive signed price return: a price increase for a bullish call or a decline for a bearish call.
Market-relative hit	A positive difference between signed asset and signed SPY returns over the same dates.
Rate denominator	Hits plus misses. Exact-zero moves are neutral and excluded from rates.
Return summaries	Means and medians include scored neutral returns.
Price cutoff	2026-10-01

$$r_i = d_i \left(\frac{P_{i,\text{exit}}}{P_{i,\text{entry}}} - 1 \right), \quad r_i^{\text{rel}} = d_i (r_{i,\text{asset}} - r_{i,\text{SPY}})$$

The direction multiplier is +1 for bullish calls and -1 for bearish calls. Returns are expressed as percentages. Standardized holding periods measure subsequent price performance independently of the author's stated forecast horizon.

The classifier grouped posts by New York publication date and linked each view to verbatim source text. It received no historical prices or realized outcomes. Adjudications preceded outcome review. Retrospective use of a current AI model leaves potential exposure to subsequent information in its training data.

Company references were matched to historical issuers. Verified ticker changes share a security identity; acquisitions and distinct share classes remain separate. References to Google that omit a share class use the classifier's GOOG or GOOGL selection, made without outcome data. This is an explicit share-class assumption. Daily opening prices serve as research proxies and are not verified executable fills at 9:30 a.m.

Source: SocialData archived public X text; Massive split-adjusted daily prices and historical issuer records.

Eligibility and exclusions

The archive contains 2,069 identified asset views, including 1,465 stock and ETF views. The primary analysis covers U.S. equities and ETFs on the SPY trading calendar. Cryptocurrency results are reported separately.

Status at 21 sessions	Calls
Hit	646
Miss	637
Neutral	0
Pending horizon	18
Unscored or outside equity scope	768
Records in the primary scoring ledger	2,069

Exclusion categories

Reason	Calls
Outside the U.S. equity / ETF scope	604
Conditional, exit or unclear source statement	159
Missing exact entry-session price	2
Source or ticker mapping needing review	2
Missing exact exit-session price	1

Record-level exclusions appear in all-calls.csv and outcomes.csv and do not enter the hit-rate denominator.

Of 1,304 stock and ETF views that meet the source eligibility criteria, 1,283 have a scored one-month outcome, 18 remain pending and three lack required prices. Exclusions include conditional views, ambiguous statements, completed exits, non-equity themes and unresolved instruments. Two SK Hynix views lack a verified U.S. ticker.

Treating the three mature observations with missing prices as either all misses or all hits produces directional hit-rate bounds of 50.23% to 50.47%. This calculation measures sensitivity to the missing outcomes without imputing returns or reconstructing delisting proceeds.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Directional and market-relative performance

Directional and market-relative hit rates by horizon

Standardized forward windows; market-relative results use matching dates and direction.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Applying each stock call's direction to SPY over the same dates produces a 55.6% directional hit rate, compared with 50.4% for the stock calls. Median market-relative return was -0.36%, and the mean was approximately zero. The sample does not demonstrate a positive average stock-selection contribution relative to SPY.

At 21 sessions, directional hits total 646 of 1,283; market-relative hits total 614 of 1,283. SPY accuracy using the same directions is 55.6%.

Benchmark interpretation

Directional accuracy does not require market outperformance. A bullish stock can rise but lag SPY. A bearish call can fail directionally yet succeed relatively when the stock rises less than SPY. A 2% stock gain against a 5% SPY gain produces -2% signed price return and +3% signed relative return for a bearish call. Both measures use the original direction and identical dates.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Holding-period analysis

Sessions	Dir. n	Rel. n	Hit	Vs SPY	Mean	Mean vs SPY
1	1,298	1,300	51.8%	49.5%	+0.27%	+0.21%
5	1,292	1,296	48.8%	46.4%	+0.12%	-0.02%
21	1,283	1,283	50.4%	47.9%	+0.40%	+0.01%
63	1,239	1,239	53.0%	49.2%	+2.65%	+1.34%
126	1,115	1,115	54.3%	46.5%	+3.71%	+0.81%
252	896	896	58.5%	48.8%	+10.41%	+3.01%

Sample size varies with maturity and price availability. Price reversals can also change a call's outcome over longer windows. Results across horizons measure different holding periods and are not independent replications.

Common observation cohort

Sessions	Dir. n	Rel. n	Hit	Vs SPY
1	894	896	51.5%	48.8%
5	893	896	48.7%	45.4%
21	896	896	50.0%	46.5%
63	896	896	51.8%	47.8%
126	896	896	51.7%	45.2%
252	896	896	58.5%	48.8%

The common cohort contains 896 calls with complete required prices at every horizon. It favors older observations and excludes calls with any required price missing. Dir. n and Rel. n count directional and market-relative hits plus misses separately; each rate excludes exact-zero outcomes.

At 252 trading sessions, directional accuracy is 58.5% and market-relative accuracy is 48.8%. The common cohort of 896 calls observed at every horizon has a one-month directional hit rate of 50.0%. Longer holding periods alter the measurement and the available sample. The use of price returns excludes dividends, an omission that matters more for income stocks and longer windows.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Performance by recommendation type

Hit rates by call type

21-session outcomes by source-text call type; categories are descriptive.

Dots: hit rates. Whiskers: 95% Wilson intervals assuming independent calls.

Groups are ordered by directional hit rate; the ranking does not establish significance.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Hold recommendations recorded 56.6% directional accuracy across 83 outcomes, compared with 48.6% across 140 explicit buy recommendations. Avoid recommendations recorded 55.6% across 27 outcomes. Sell recommendations recorded 57.9% across 19, a small sample with substantial ranking uncertainty. Add recommendations have six scored observations. The scored sample contains no unconditional explicit short recommendation.

The categories describe the action expressed in the source. Sell and avoid recommendations do not imply an initiated short position. A position trim can precede a price increase; the directional score records that outcome but does not assess the portfolio rationale for reducing exposure.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Performance by investment thesis

Market-relative hit rates by thesis and horizon

Source-text thesis categories; standardized forward windows.

Gray cells have fewer than 20 binary outcomes; no rate is displayed.

Percentages are rounded; n = hits + misses. Comparisons do not adjust for multiple testing.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Valuation has the highest one-month directional point estimate among the named thesis categories: 55.6%, with mean signed return of +2.65% and mean market-relative return of +2.20%. Momentum recorded 44.9% directional accuracy, mean signed return of -2.29% and mean market-relative return of -2.46%. Fundamental calls recorded 46.3% accuracy across 320 outcomes.

Each thesis label reflects the reasoning in the source post. Where a view contains several rationales, the classifier assigns one primary category. Differences in category composition, correlated securities and multiple comparisons limit the predictive interpretation of these rankings.

Cells with fewer than 20 binary outcomes show their sample size without a rate.

Performance by publication year

Directional hit rates by year and bias

21-session outcomes by publication year and bullish or bearish direction.

Whiskers: 95% Wilson intervals assuming independent calls. Open dots: $n < 20$.

Year and bias groups describe the sample; the analysis does not isolate market regimes.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

The 2022 publication cohort has the lowest observed directional accuracy: 40.6% across 239 scored calls, with mean signed return of -3.23%. Other annual cohorts recorded accuracy between 51.5% and 53.9%. The full sample contains 1,083 scored bullish calls and 200 bearish calls.

Bearish calls recorded 52.0% directional and 51.5% market-relative accuracy, compared with 50.0% and 47.2% for bullish calls. These comparisons do not isolate forecasting skill from market conditions or changes in source coverage. The 2021 and 2026 cohorts cover partial publication years.

Annual comparisons reflect differences in security selection, market conditions, call frequency and archive coverage. They describe observed results without identifying the effect of a particular economic regime.

Return distribution

Distribution of directional and market-relative returns

Every scored 21-session outcome, including neutral returns and full tails.

Negative directional returns oppose the call; negative relative returns lag same-direction SPY.
The symmetric-log x-axis includes extreme returns; the central $\pm 10\%$ is linear.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Median signed return at one month was +0.12%, compared with a mean of +0.40%. The 10th and 90th percentiles were -13.97% and +14.66%, respectively. Mean signed return was +10.41% for correct calls and -9.74% for incorrect calls. Large positive observations can support the mean despite a hit rate close to 50%.

21-session signed returns	Value
Median	+0.12%
Mean	+0.40%
10th percentile	-13.97%
90th percentile	+14.66%

Security concentration

Concentration of scored calls by security

258 securities account for 1,283 scored calls; the top five account for 26%.

Verified ticker renames are grouped as one security. Top ten shown; others pooled. Sensitivity checks use equal security weights and suppress repeated calls.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

The scored sample contains 258 verified securities. Repeated posts can express the same investment thesis and share overlapping return windows. Securities with more calls therefore receive more weight in the aggregate calculation; the exhibit reports that concentration.

Calls on the same security may share forward price movements. Equal-security weighting measures sensitivity to the greater influence of frequently cited securities in a call-weighted average.

Sensitivity analysis

Hit rates under alternative sampling and weighting rules

21-session selection, weighting and repeat-call sensitivities.

The episode rule suppresses repeats for 21 sessions. Each security is equally weighted in row 3. Text confidence measures interpretation, not forecast success. Intervals are not shown.

Source: Archived X text; split-adjusted prices; X Account Backtest skill calculations

Suppressing repeated views on the same security and in the same direction within 21 sessions leaves 844 scored events. Directional accuracy is 49.8%, market-relative accuracy is 45.9% and mean market-relative return is -0.68%. Giving each security equal weight produces 48.4% directional accuracy and mean market-relative return of -0.82%.

The 446 scored explicit recommendations recorded 51.8% directional and 48.0% market-relative accuracy. The 827 calls with higher classification confidence recorded 49.5% and 47.0%, respectively. Classification confidence is uncalibrated and does not measure the probability of a correct forecast.

The repeat-call test retains the earliest observed call on a security in a given direction, then suppresses additional calls in that group for 21 SPY sessions. Verified ticker renames remain a single security.

The equal-security test averages each verified security's rate once, grouping verified ticker aliases under one identity.

Statistical uncertainty

Metric	Estimate	Wilson 95%	Month-cluster 95%
Directional hit rate	50.4%	47.6% to 53.1%	45.9% to 54.8%
Market-relative hit rate	47.9%	45.1% to 50.6%	44.6% to 51.1%
Mean signed price return	+0.40%	Not applicable	-1.3% to +2.3%
Mean signed relative return	+0.01%	Not applicable	-1.3% to +1.5%

The cluster bootstrap resamples 59 entry months over 2,000 iterations and retains calls within each sampled month.

Wilson intervals assume independent calls and provide descriptive sampling ranges; they do not establish predictive skill. Clustering by entry month does not fully account for securities repeated across months or overlapping holding periods across month boundaries. The bootstrap is a descriptive robustness measure.

The primary intervals clustered by entry month include 50% directional and market-relative accuracy, as well as zero mean returns. The sample therefore does not establish an aggregate forecasting advantage at one month. This finding does not establish zero skill across other settings. Overlapping return windows and repeated securities across months leave residual dependence.

Study limitations

Archive completeness cannot be verified. Deleted, private, filtered or otherwise inaccessible posts may introduce selection bias. Conditional and ambiguous views remain identified in the dataset without an assigned forecast outcome.

The study measures subsequent price changes. It excludes dividends, transaction costs, borrowing constraints and some corporate-action proceeds, and therefore does not measure investor wealth or compounded strategy returns. Market-relative return is the signed difference between the asset and SPY returns, without beta or sector adjustment; it is not risk-adjusted alpha.

Subgroup rankings and additional horizons are exploratory. The reported returns are hypothetical price outcomes, without evidence of executed trades or an implementable strategy.

Selected call reviews

2025-05-01 · CRWV · bullish

"Tell em to go buy some CoreWeave"

The explicit CoreWeave buy was followed by a large positive one-month move. Such observations can materially affect the sample mean without establishing ongoing portfolio performance.

Status: hit; signed return: +166.94%; signed return versus SPY: +162.05%.

Source: [Original X post](#)

2026-01-25 · INTU · bullish

"Intuit good last q, still a buy"

Intuit declined 36.8% after the explicit buy over the standardized one-month window. The call was directionally incorrect; its longer-term thesis remains outside this assessment.

Status: miss; signed return: -36.80%; signed return versus SPY: -36.75%.

Source: [Original X post](#)

2025-07-31 · FIG · bearish

"If you are putting in a market order from Figma you should pull it now. You will get it lower .It is ..."

The Figma avoid recommendation cited valuation. Its 48.9% price decline was consistent with the bearish view over one month.

Status: hit; signed return: +48.85%; signed return versus SPY: +50.64%.

Source: [Original X post](#)

2025-12-15 · MU · bearish

"a cyclical DRAM cycle almost requires you to take some off into the quarter of MU"

Micron rose 49.7% after the trim recommendation. The bearish price direction was incorrect over the measured window. Reducing cyclical exposure may serve a separate portfolio risk-management objective.

Status: miss; signed return: -49.75%; signed return versus SPY: -47.62%.

Source: [Original X post](#)

These cases illustrate individual outcomes, without establishing aggregate performance. The accompanying ledger contains all classified views, including unscored and pending records.

Cryptocurrency results

The 30-calendar-day analysis contains 14 identifiable, unambiguous cryptocurrency views. Five were correct and nine incorrect, for a 35.7% hit rate and a descriptive Wilson interval of 16.3% to 61.2%. Mean signed USD spot return was -11.84%, and the median was -18.17%. The sample is too small to support stable category rankings.

BTC, ETH and DOGE prices use Coinbase daily USD candles. General cryptocurrency views without a specific token remain unscored.

The reported cryptocurrency primary window is 30 calendar days.

Entry uses the first UTC daily open strictly after the New York publication day ends: the publication date plus two calendar days at 00:00 UTC. This delay places the measured return after all source text in that day's classification batch.

Returns use exchange-specific USD spot opening prices and exclude fees and borrowing costs. Cryptocurrency outcomes use calendar days and have no SPY comparison.

Metric	Result
Scored crypto calls	14
Directional hit rate	35.7%
Calls in the hit-rate denominator	14
Mean signed price return	-11.84%
Median signed price return	-18.17%

Cryptocurrency trades continuously. Its calendar-day observations remain separate from the primary U.S. equity study and are excluded from the SPY-session hit rate.

Source: Coinbase USD daily candles; X Account Backtest skill calculations, recorded in crypto-outcomes.json.

Sources and verification

The figures use the finalized call ledger and historical price data. An independent implementation reconciled all 12,414 call-by-horizon records and aggregate calculations, with no mismatches across 231,565 checks. A separate cryptocurrency audit reconciled 155 records across calendar horizons in 736 checks.

A blinded review of source text from 120 posts identified six disagreements about call inclusion or attribution. Adjudication before outcome review added three inferred stock views, excluded one product comment and upheld two exclusions. A targeted review of 131 inferred views across 104 posts confirmed the product-comment correction. These audits do not estimate population precision or recall.
